A Details on Estimation Method

A.1 Austerity and Economic Performance

Our main cross-sectional regression (ignoring controls) is

$$\frac{1}{5} \left(\sum_{t=2010}^{2014} \ln X_{i,t} - \ln \widehat{X}_{i,t} \right) = \alpha_0 + \alpha \frac{G_i}{Y_i} \frac{1}{5} \left(\sum_{t=2010}^{2014} \ln G_{i,t} - \ln \widehat{G}_{i,t} \right) + \varepsilon_{i,t}.$$
(A.1)

Here, $X_{i,t}$ refers to country *i*'s economic performance at time *t* (GDP, inflation, consumption,...), and $\hat{X}_{i,t}$ is its forecast. Note that for consumption and investment, we pre-multiply the left-hand side by X_i/Y_i , the share of consumption / investment in GDP, averaged over 2000 - 2010. Similarly, $G_{i,t}$ is a government finance variable for country *i* at time *t* (e.g. shortfalls in government purchases, shortfalls in government revenue). Denote the growth rate, defined as the change in logs, for any variable *X* by g^X . To construct our forecasts of $\ln X_{i,t}$ and $\ln G_{i,t}$ we only use data on the forecasted variable up to T_{cut} to construct forecasts for $t > T_{cut}$. For instance, in our benchmark estimation for government finance variables, we only use data of $G_{i,t}$ up to 2009 to construct forecasts up to 2014.

Using the definition of g, we can express the value of $\ln X_{i,t}$ as its value in $t = T_{cut}$ plus the cumulative growth rate between T_{cut} and t: $\ln X_{i,t} = \ln X_{i,T_{cut}} + \sum_{s=T_{cut}+1}^{t} g_{i,s}^{X}$. Now, let

$$\bar{g}_{i,2010:2014}^X = \frac{1}{5} \sum_{t=2010}^{2014} \sum_{s=T_{cut}+1}^t g_{i,s}^X$$

be country *i*'s average multi-year growth rate of variable X. These multi-year growth rates $\sum_{s=T_{cut}}^{t} g_{i,s}^{X}$ refer to the growth rate between the cutoff year T_{cut} and time *t*, with *t* being the years 2010 to 2014. Given this definition, we can rewrite the cross-sectional regression as

$$\bar{g}_{i,2010:2014}^X - \hat{\bar{g}}_{i,2010:2014}^X = \alpha_0 + \alpha \frac{G_i}{GDP_i} \left(\bar{g}_{i,2010:2014}^G - \hat{\bar{g}}_{i,2010:2014}^G \right) + \varepsilon_i$$

Now, we discuss how we derive estimates of $\ln \widehat{X}_{i,t}$ and $\ln \widehat{G}_{i,t}$, and their corresponding estimated growth rates, $\widehat{g}_{i,t}^X$ and $\widehat{g}_{i,t}^G$.

A.2 Economic Performance

Our forecasting specification for GDP, consumption and investment is

$$\ln \widehat{X}_{i,t} = \begin{cases} \ln X_{i,t-1} + \widehat{g}_{EU}^X + \widehat{\gamma}^X \left(\ln \widehat{X}_{EU,t-1} - \ln X_{i,t-1} \right) & \forall t - 1 \le T_{cut} \\ \ln \widehat{X}_{i,t-1} + \widehat{g}_{EU}^X + \widehat{\gamma}^X \left(\ln \widehat{X}_{EU,t-1} - \ln \widehat{X}_{i,t-1} \right) & \forall t - 1 > T_{cut}. \end{cases}$$
(A.2)

Here, $X_{i,t}$ is country *i*'s GDP, consumption or investment at time *t*, and $\hat{X}_{i,t}$ is its forecast. The specification takes last period's value of (the log of) $X_{i,t}$ and adds a country- and time-specific growth rate, which is composed of two parts: a common term capturing the average rate of growth of the core European countries, \hat{g}_{EU}^X , and a catch-up term that raises this growth rate for poorer countries and lowers it for richer countries, $\gamma \left(\ln \hat{X}_{EU,t-1} - \ln X_{i,t-1} \right)$. Finally, T_{cut} , denotes the cutoff date. Only data up to T_{cut} is used to construct forecasts for $t > T_{cut}$.

This specification is based on the conditional convergence hypothesis. We assume that countries in Europe converge to a common path for GDP per capita. This can be justified on basis of the Single European Act (Article 158), which foresees economic cohesion across all member states as a central goal of the EU. Economic cohesion is typically interpreted as reducing disparities in GDP per capita. This convergence process especially affects our forecasts for Central and Eastern European countries, which, after strong economic growth in the 90s and 2000s, have reduced the gap to Western European countries. For instance, between 1995 and 2014, Estonia increased its GDP per capita from 30% to more than 60% of the EU-12 average.

Estimation of g_{EU}^X . In a first step, we estimate the growth rate g_{EU}^X on data from 1993:1 to 2005:4:

$$\ln X_{EU,t} = \beta_0 + g_{EU}^X t + \epsilon_{EU,t}^X,$$

Here, X_{EU} is the aggregate of the 12 core European economies (Belgium, Denmark, Germany, Ireland, Spain, France, Italy, Luxembourg, Austria, Netherlands, Portugal and Finland). The estimate of g_{EU}^{Y} is 0.49 percent with a standard deviation of 0.01 percent, i.e. the average annual growth rate over this time period was about 2 percent. Note that this also gives a forecast of $\ln X_{EU,t}$ that is used in (A.2). Estimation of γ^X . In a second step, we estimate the time-varying part of the growth rate. We assume that the time-varying part is a linear function of the log difference between the predicted EU-12 X and a country's X:

$$g_{i,t}^{X} - \hat{g}_{EU}^{X} = \gamma^{X} \left(\ln \hat{X}_{EU,t-1} - \ln X_{i,t-1} \right) + \epsilon_{i,t}^{X}.$$

where $\ln \hat{X}_{EU,t-1} = \hat{\beta}_0 + \hat{g}_{EU}^X(t-1)$. We estimate a common γ^X for all countries in Central and Eastern Europe (Bulgaria, Czech Republic, Estonia, Greece, Cyprus, Latvia, Lithuania, Hungary, Poland, Romania and Slovenia, Slovak Republic) using 1993:1 (or earliest available data) to 2005:4 as our sample period. Our estimate of γ^Y is 0.51 percent with a standard deviation of 0.05 percent. The positive γ indicates convergence.¹

For future reference, we define the estimated growth rate of country i's X at time t as

$$\hat{g}_{i,t}^{X} = \begin{cases} \hat{g}_{EU}^{X} + \hat{\gamma}^{X} \left(\ln \widehat{X}_{EU,t-1} - \ln X_{i,t-1} \right) & \forall t - 1 \leq T_{cut} \\ \hat{g}_{EU}^{X} + \hat{\gamma}^{X} \left(\ln \widehat{X}_{EU,t-1} - \ln \widehat{X}_{i,t-1} \right) & \forall t - 1 > T_{cut}. \end{cases}$$
(A.3)

This is also our forecast for the growth rate of GDP used in our regression analysis.

Our forecast for inflation, exchange rates and net exports are:

$$\widehat{X}_{i,t} = \frac{1}{8} \sum_{s=2008Q1}^{2009Q4} X_{i,s}$$

for dates t after 2009. Note that for these variables, we are using the absolute value instead of the log in regression (A.1).

A.3 Austerity

We also use this 'convergence' estimator to predict the government finance variables (except for the primary balance). In particular, we construct our forecast as

$$\ln \widehat{G}_{t}^{i} = \begin{cases} \ln G_{i,t-1} + \widehat{g}_{i,t}^{Y} + \widehat{\theta}^{G} \left(\ln Y_{i,t} - \ln \widehat{Y}_{i,t} \right) & \forall t - 1 \leq T_{cut} \\ \ln \widehat{G}_{i,t-1} + \widehat{g}_{i,t}^{Y} + \widehat{\theta}^{G} \left(\Delta \ln Y_{i,t} - \Delta \ln \widehat{Y}_{i,t} \right) & \forall t - 1 > T_{cut} \end{cases}$$
(A.4)

¹We repeat this two-step procedure to forecast private consumption and total investment. The estimated values for g and γ are 0.45 (0.01) percent and 0.71 (0.06) percent for private consumption, and 0.67 (0.03) percent and 1.17 (0.22) percent for total investment.

and θ^G is a (estimated / calibrated) elasticity of the government finance variable with respect to deviations of GDP from its trend.

The first part of our forecast adds a country- and time-specific growth rate $\hat{g}_{i,t}^Y$ to last year's actual realization of $\ln G_{i,t-1}$ (within sample) or last year's predicted value of $\ln G_{i,t-1}$ (out of sample). This growth rate $\hat{g}_{i,t}^Y$ is the estimated growth rate of country *i*'s GDP per capita at time *t*, calculated as in (A.3), but using annual data for GDP.² We prefer using the growth rate of GDP instead of *G* in this step because countries strongly differ in terms of their ratios of government purchases, total outlays and total revenue to GDP. Economic cohesion in terms of GDP per capita is an explicit goal of the European Union, but the European Union does not try to achieve convergence in the level of all government finance variables.

The second part of our forecast, $\theta^G \left(\ln Y_{i,t} - \ln \widehat{Y}_{i,t} \right)$, adjusts for deviations of GDP from its trend. This is particularly relevant for government revenue variables. We either estimate θ^G or use values from the literature discussed in the main body of the text.

Our forecast for the growth rate of G is therefore composed of three parts:

$$\hat{g}_{i,t}^{G} = \begin{cases} \hat{g}_{EU}^{Y} + \hat{\gamma}^{Y} \left(\ln \widehat{Y}_{EU,t-1} - \ln Y_{i,t-1} \right) + \hat{\theta}^{G} \left(\ln Y_{i,t} - \ln \widehat{Y}_{i,t} \right) & \forall t - 1 \leq T_{cut} \\ \hat{g}_{EU}^{Y} + \hat{\gamma}^{Y} \left(\ln \widehat{Y}_{EU,t-1} - \ln \widehat{Y}_{i,t-1} \right) + \hat{\theta}^{G} \left(\ln Y_{i,t} - \ln \widehat{Y}_{i,t} \right) & \forall t - 1 > T_{cut}. \end{cases}$$

Estimation of θ^G : To estimate θ^G , we use two approaches. In the first approach, we regress our forecast error of $\ln G_{i,t}$ based on a forecast that ignores the GDP adjustment on the deviations of GDP from its trend:

$$\ln G_{i,t} - \ln G_{i,t-1} - \hat{g}_{i,t}^{Y} = \theta_{0,i}^{G} + \theta^{G} \left(\ln Y_{i,t} - \ln \widehat{Y}_{i,t} \right) + \epsilon_{i,t}^{\theta}$$
(A.5)

This is estimated on data up to 2005.

In the second approach, we construct average multi-year growth rates of GDP and G for 5-year windows:

$$\bar{g}_{i,t:t+4}^{Y} = \frac{1}{5} \sum_{r=t}^{t+4} \sum_{s=T_{cut}(t)}^{r} g_{i,s}^{Y},$$

²The estimated values for g and γ are 1.89 percent and 2.32 percent.

where we adjust the cutoff-year T_{cut} accordingly.³ Then, we estimate the regression

$$\bar{g}_{i,t:t+4}^{G} - \hat{\bar{g}}_{i,t:t+4}^{Y} = \theta_{0,i}^{G} + \theta^{G} \left(\bar{g}_{i,t:t+4}^{Y} - \hat{\bar{g}}_{i,t:t+4}^{Y} \right) + \varepsilon_{i,t}^{\theta}.$$
(A.6)

on data up to t = 2001.

B Additional Empirical Results

Here, we present additional empirical results based on the estimation equation (A.1). We do not include any controls and report the estimates for α for the entire sample, as well as for the subsamples of fixed and floating exchange rates. Results are reported for various government finance variables: shortfall in government purchases (Table A6a), total government outlays (measured as the sum of government purchases and social benefits, Table A6b), the government primary balance (measured as government revenue less government expenditure net of net government interest payments, and expressed in percent of nominal GDP; Table A6c), total government revenue (Table A6d), the VAT rate (measured as described in Section ??; Table A6e), the statutory income tax rate (Table A6f) and the statutory corporate tax rate (Table A6g). Note that we omit the term G_i/Y_i in regression (A.1) for the primary balance and all tax rates. The analyzed economic performance measures include all measures discussed in the main body of the text, plus the unemployment rate and the debt to GDP ratio (both forecasted using the unit root forecast (A.2)).

C Structural Shocks in Model

C.1 Government Spending Shocks

In our empirical section we estimate deviations for government finance variables from their forecasts constructed from annual data. In the quantitative analysis, we treat those deviations as shocks and feed them into our model. The model, however, is calibrated at quarterly frequency. We use the Chow-Lin method to transform our predicted annual government spending series to quarterly series. As auxiliary high-frequency indicators we solely rely on real, quarterly GDP. Adding quarterly unemployment rates would barely affect the resulting

³If we choose the cutoff year $T_{cut} = 2009$ in (A.1), then the cutoff-year for the window stretching t = 1990 to t + 4 = 1994 would be $T_{cut}(1990) = 1989$.

time-series and the estimated coefficients are most of the time statistically non-significant. We estimate the model with maximum likelihood. The government spending shocks that we feed into our model are then the deviations of actual quarterly government spending data from their predicted quarterly levels.

C.2 Monetary Policy Rules

We measure monetary policy shocks as deviations of the central bank interest rates' from a monetary policy rule. These deviations are calculated for each country with an independent monetary policy⁴ (Czech Repbulic, Hungary, Poland, Romania, Sweden, United Kingdom, Norway, Switzerland and the United States) as well as the ECB.

Here, we present results for various different specifications of monetary policy rules. Eventually, we retain the generalized Taylor rule specification proposed by ?.

C.2.1 Specifications

Simple Taylor rule

$$i_t = \pi_t + r + \phi_\pi \left(\pi_t - \pi^{tar}\right) + \phi_{GDP} \% GDP_t + \epsilon_t$$

where i_t is the nominal interest rate, r is the long-run real interest rate, π_t is inflation, π^{tar} is the inflation target, $\% GDP_t$ are percent deviations of real GDP from its trend (output gap), and ϵ_t is an error term. Inflation is measured using the GDP deflator. Interest rates, inflation and the unemployment rate are measured in annual percent.

In the original Taylor rule, the parameters are set to r = 2 and $\pi^{tar} = 2$, and the estimated coefficients are $\phi_{\pi} = 0.5$ and $\phi_{GDP} = 0.5$. Bernanke $(2015)^5$ suggests to use core inflation as a measure of π and sets $\phi_{GDP} = 1$.

Generalized Taylor rule ? (henceforth CGG) propose a generalized Taylor rule that

⁴This includes all countries with central banks that were free or managed floaters or whose monetary policy followed a wide crawling peg, according to the classification in ?.

⁵see http://www.brookings.edu/blogs/ben-bernanke/posts/2015/04/28-taylor-rule-monetary-policy

allows for interest rate smoothing:⁶

$$i_{t} = \rho i_{t-1} + (1-\rho) \left[\pi_{t} + r + \phi_{\pi} \left(\pi_{t} - \pi^{tar} \right) + \phi_{GDP} \% GDP_{t} \right].$$

Their estimates are $\rho = 0.79$, $\phi_{\pi} = 1.15$ and $\phi_{GDP} = 0.93$. They don't provide an estimate for the intercept or r.

Mankiw rule

$$i_t = \phi + \phi_{\pi,u}(\pi_t - u_t) + \epsilon_t,$$

where i_t is the nominal interest rate, π_t is core inflation, u_t is unemployment, and ϵ_t is an error term. Mankiw estimates $\phi = 8.5$ and $\phi_{\pi,u} = 1.4$.

C.2.2 Estimation

For the US, we estimate three different rules: A simple Taylor rule, a generalized Taylor rule as in CGG, and a Mankiw rule. For the euro area and all countries with floating exchange rates, we us the slope coefficients ϕ from the regressions and estimate a new intercept. We always impose that inflation targets a rate of 2%.⁷

Taylor rule Starting from the generalized Taylor rule

$$i_{t} = \phi_{i}i_{t-1} + (1 - \phi_{i})\left[\pi_{t} + r + \phi_{\pi}\left(\pi_{t} - \pi^{tar}\right) + \phi_{GDP}\%GDP_{t} + \epsilon_{t}\right],$$

our estimation equation is

$$\frac{i_t - \phi_i i_{t-1}}{1 - \phi_i} - \pi_t = \beta_0 + \beta_1 \left(\pi_t - \pi^{tar} \right) + \beta_2 \% GDP_t + \epsilon_t.$$
(C.1)

Our estimates for r, ϕ_{π} and ϕ_{GDP} are $\hat{\beta}_0$, $\hat{\beta}_1$ and $\hat{\beta}_2$. In our estimation approach, we set $\phi_i = 0$ for the original Taylor rule and $\phi_i = 0.79$ for the CGG specification.

⁶In addition, their rule depends on expected inflation and the expected output gap instead of contemporaneous inflation and output gap. Their β coefficient corresponds to $1 + \phi_{\pi}$ in our setup.

⁷Unless we make further restrictions, we cannot estimate r and π^{tar} separately, so we fix one of the two parameters prior to the estimation. CGG assume that r equals its average value of their estimation period and then estimate π^{tar} . They do not report their estimate of r. Their estimate of π^{tar} is 3.56. Here, we us the alternative approach of fixing $\pi^{tar} = 2$ and estimate r for every specification, including the original CGG specification.

When we only estimate the intercept, the estimation equation is

$$\frac{i_t - \phi_i i_{t-1}}{1 - \phi_i} - \pi_t - \hat{\phi}_\pi \left(\pi_t - \pi^{tar} \right) - \hat{\phi}_{GDP} \% GDP_t = \beta_0 + \epsilon_t \tag{C.2}$$

Mankiw rule Our estimation equation for the Mankiw rule is

$$i_t = \beta_0 + \beta_1 (\pi_t - u_t) + \epsilon_t. \tag{C.3}$$

Our estimates for ϕ and $\phi_{\pi,u}$ are $\hat{\beta}_0$ and $\hat{\beta}_1$.

When we only estimate the intercept, the estimation equation is

$$i_t - \hat{\phi}_{\pi,u}(\pi_t - u_t) = \beta_0 + \epsilon_t. \tag{C.4}$$

Data and estimation periods Data on the central bank interest rates, i_t , directly comes from the central banks' websites (see the Data appendix for more details). Data sources for the inflation rate, π_t and the unemployment rate u_t are explained in the appendix. The output gap, $\% GDP_t$, is measured as the percent deviation of GDP from its potential GDP. Data on potential GDP for the US comes from the Gongressional Budget Office. For all other countries, we rely on annual data published by AMECO and the OECD. We linearly interpolate the log of potential GDP to obtain quarterly estimates.

The estimation periods are as follows. USA: 1985Q1 - 2005Q4, Eurozone: 1999Q2 - 2005Q4, Czech Republic: 2000Q2 - 2005Q4, Hungary: 2002Q2 - 2005Q4, Poland: 2002Q2 - 2005Q4, Romania: 2003Q2 - 2005Q4, Sweden: 1994Q3 - 2005Q4, UK: 1985Q1 - 2005Q4, Norway: 1991Q2 - 2005Q4, Switzerland: 1991Q1 - 2005Q4.

Tables A1 and A2 display the estimated coefficients for the US Monetary policy and the intercepts for all central banks in our sample.

C.3 Spread Shocks

Our measure of financial shocks comes from data on spreads between lending rates and central bank interest rates.

Data on interest rates on business loans mainly comes from the ECB, but has been complemented by additional sources. The ECB reports monthly interest rates for new business loans up to 1 year original maturity to non-financial corporations in domestic currency (e.g.

MIR.M.AT.B.A2A.F.R.0.2240.EUR.N for Austria - AT). For countries accessing the euro area over the sample period, we try to use loans in domestic currency up to the year they access the euro area, and then switch to loans in euros. For some countries (e.g. Bulgaria, Estonia, Cyprus, Malta, Slovak Republic, Sweden, UK, Norway and Switzerland) we used national bank data sources to append the data series (or replace them if missing). For a few countries, we used data from the Fixed Income Global Financial Database to append the data series. ⁸

 $^{^8 \}rm We$ checked that the GFD data tracks reasonably well our preferred interest rate series for time periods with overlap.

Finally, US data comes from the Federal Reserve Survey of Terms of Business Lending, where we use the weighted-average effective loan rate for all commercial and industry loans.

For central bank interest rates, we use the central banks' main policy rates. For countries accessing the euro area over the sample period, we use the national central bank's interest rate up to the year they access the euro area.⁹

See the data appendix for a detailled list of data series.

D Non-Targeted Steady-State Shares

Figure A3 displays the non-target steady-state shares of net exports to final demand, NX_n/Y_n , and investment to final demand, X_n/Y_n . It compares the average shares observed in the data over 2000 - 2010 to the model-implied shares. The correlation between model and data is 0.9975 for net exports. This is a surprisingly high correlation because the net export shares in the model are derived from parameters calibrated using data for 2005 and 2010 only: Net export shares in the model are functions of the trade preference parameters ω_n^j and relative country sizes $N_n Y_n$, both of which are calibrated using input-output tables and the trade in value added database covering the years 2005 and 2010. The correlation between model and data for investment is substantially lower, but still positive: 0.53. The depreciation rate is calibrated so that the average investment shares in data and model match each other. Three features of the model create dispersion in investment shares: cross-country differences in net export positions NX_n/Y_n , cross-country differences in the external finance premium F_n , and cross-country differences in the taxation of capital income, τ_n^K . The figure suggests that the model underpredicts investment shares of countries in Central and Eastern Europe such Bulgaria, Romania and Latvia, but overpredicts investment shares of most advanced countries like Luxembourg, Norway and Great Britain. The high investment shares in Central and Eastern Europe might indicate a catching up process towards the European core countries that we ignore in our model.

⁹In our model, we assign those countries directly to the euro area, ignoring the fact that in the beginning of the sample period they had an independent monetary policy.

E Wage Setting

In our robustness analysis, we introduce sticky wages. To do so, we follow the treatment by ? and ? by assuming that the household supplies labor to firms through unions that have some market power. Specifically, we assume that *effective* labor is a CES mix of different labor types. These labor types are aggregated by aggregation firms that then supply the labor aggregate to the firms at a nominal wage of $W_{n,t}$. Effective labor is given by

$$L_{n,t} = \left(\int_{0}^{1} l_{n,t} \left(z\right)^{\frac{\psi_{l}-1}{\psi_{l}}} dz\right)^{\frac{\psi_{l}}{\psi_{l}-1}}$$

where $L_{n,t}$ is the effective amount of labor supplied to the firms in country n at time tand $l_{n,t}(z)$ is the amount of type s labor supplied. The parameter $\psi_l > 1$ governs the degree to which different labor types are substitutable. The labor aggregating firm behaves competitively and supplies effective labor to the firms at the flow nominal wage $W_{n,t}$ but hires labor by type according to the type-specific nominal wages $w_{n,t}(z)$. Demand for each labor type is

$$l_{n,t}(z) = L_{n,t} \left(\frac{w_{n,t}(z)}{W_{n,t}}\right)^{-\psi_l}$$
(E.1)

and the competitive aggregate nominal wage in country n at time t is

$$W_{n,t} = \left(\int_0^1 w_{n,t} (z)^{1-\psi_l} dz\right)^{\frac{1}{1-\psi_l}}$$

Wages for each type of labor are set by monopolistically competitive worker-types. Given the elasticity of demand $-\psi_l$, workers desire a real wage $(1 - \tau_n^L)w_{n,t}(z)/P_{n,t}$ which is a constant markup over the marginal rate of substitution between consumption and leisure, $-U_{2,n,t+j}/U_{1,n,t+j}$ (i.e., the competitive wage). The desired markup is $\mu_w = \frac{\psi_l}{\psi_l - 1} > 1$.

As in ?, we model sticky wages with a Calvo mechanism. Let θ_w be the probability that a worker cannot reset his or her wage in a given period. Whenever possible, workers reset wages to maximize the utility of the representative household in country n. The marginal benefit of additional money at time t + j is $\frac{C_{n,t+j}^{-\frac{1}{\sigma}}}{(1+\tau_n^C)P_{n,t+j}}$ and the marginal disutility to the representative household from supplying additional labor is $\kappa_n L_{n,t+j}^{\frac{1}{\eta}}$. Workers take the demand curve (E.1) as given whenever they can choose a new reset wage. Denote the optimal reset wage in country n at time t as $w_{n,t}^{\ast}.$ The optimal reset wage satisfies

$$w_{n,t}^{*} = \frac{\psi_{l}}{\psi_{l} - 1} \frac{-\sum_{j=0}^{\infty} (\theta_{w}\beta)^{j} \sum_{s^{t+j}} \pi(s^{t+j}|s^{t}) L_{n,t+j} W_{n,t+j}^{\psi_{l}} \kappa_{n} L_{n,t+j}^{\frac{1}{\eta}}}{\sum_{j=0}^{\infty} (\theta_{w}\beta)^{j} \sum_{s^{t+j}} \pi(s^{t+j}|s^{t}) L_{n,t+j} W_{n,t+j}^{\psi_{l}} (1 - \tau_{n}^{L}) \frac{C_{n,t+j}^{-\frac{1}{\eta}}}{(1 + \tau_{n}^{C}) P_{n,t+j}}}.$$
 (E.2)

Given (E.2), the nominal wage for effective labor evolves according to

$$W_{n,t} = \left[\theta_w \left(W_{n,t-1}\right)^{1-\psi_l} + (1-\theta_w) \left(w_{n,t}^*\right)^{1-\psi_l}\right]^{\frac{1}{1-\psi_l}}.$$

Table A3a: Summary Statistics of Forecast Deviations: Government Finance Variables

	Gov't. Purchases	Total Outlays	Primary Balance	Total Revenue	VAT	Income Tax Rate	Corporate Tax Rate
Average	-10.88	-9.99	0.27	0.10	1.55	0.92	-0.72
Std. deviation	9.04	7.53	3.30	3.80	1.53	4.99	2.65
		С	orrelation ma	trix			
Gov't. Purchases	1.00						
Total Outlays	0.95	1.00					
Primary Balance	-0.20	-0.23	1.00				
Total Revenue	-0.08	0.13	-0.09	1.00			
VAT	-0.72	-0.82	0.29	-0.05	1.00		
Income Tax Rate	-0.35	-0.20	-0.14	0.39	-0.06	1.00	
Corporate Tax Rate	0.31	0.36	-0.13	-0.08	-0.43	-0.14	1.00

Notes: Table displays statistics of the log-difference (*100) between the actual time series and the forecast, averaged over 2010 - 2014, for government purchases, total outlays, total revenue, the primary balance, the VAT, the personal income tax rate and the corporate tax rate. The first row displays the average of this difference across countries; the second row displays the standard deviation across countries. The remaining rows display the correlation across the various measures.

Table A7: INTEREST RATES AND SPREADS

Notes: Table displays the average central bank interest rates (CB rate, in percent), the average central bank interest rate less the rate implied by a monetary policy rule (Taylor deviations, in percentage points) and the spread between lending rates to businesses and the central bank interest rate (Spread, in percentage points). Averages are taken over 2004 - 2007 and 2009 - 2014. See text for details on the monetary policy rule.

	Purchases	Cons Tax	Labor Tax	Capital Tax
Belgium	24.6	20.6	53.7	34.0
Bulgaria	22.8	18.1	18.4	12.0
Czech Republic	24.4	16.5	25.2	23.0

Table A8: STEADY-STATE GOVERNMENT PURCHASES AND TAX RATES

Notes: Table displays the steady-state values for the share of government purchases in GDP, the consumption tax rate, the labor tax rate, and the capital tax rate.

Note: Left column panels display real government purchases for various countries on a log scale (normalized to 2009=100), together with their predicted values. Right column panels display the corresponding series for real GDP per capita.

Note: Left column panels display real government purchases for various countries on a log scale (normalized to 2009=100), together with their predicted values. Right column panels display the corresponding series for real GDP per capita.

Note: Left column panels display real government purchases for various countries on a log scale (normalized to 2009=100), together with their predicted values. Right column panels display the corresponding series for real GDP per capita.

Note: Left column panels display real government purchases for various countries on a log scale (normalized to 2009=100), together with their predicted values. Right column panels display the corresponding series for real GDP per capita.

Note: Left column panels display real government purchases for various countries on a log scale (normalized to 2009=100), together with their predicted values. Right column panels display the corresponding series for real GDP per capita.

Note: The figure plots the policy interest rates of the central banks in Europe and the U.S.

Note: Table displays the non-target steady-state shares of net exports to final demand, NX_n/Y_n , and investment to final demand, X_n/Y_n . Data period is 2000 - 2010. The correlation between data and model is 0.99 for net exports and 0.36 for investment.
